

TRANSMIT POWER CONTROL METHOD IN CDMA MOBILE
COMMUNICATION SYSTEM

BACKGROUND OF THE INVENTION

The present invention relates to a transmit power control method in a CDMA mobile communication system.

Description of the Related Art

Conventionally, in a transmit power control method in a CDMA mobile communication system, an outer loop control is made depending upon, for example, a reference SIR. In an up link, the outer loop control is made to update the reference SIR (Signal to Interference Ratio) to which a BTS (Base Transceiver Station) refers in a high-speed closed loop control.

A description will now be given of the high-speed closed loop control in the up link. In the high-speed closed loop control in the up link, the control is made to periodically change transmit power of an MS (Mobile Station) such that a receive SIR of an up call signal can approach the reference SIR. For example, when the receive SIR measured in the BTS is smaller than the reference SIR, the control is made to set a TPC (Transmit Power Control) bit in a down signal to an instruction pattern to increase MS transmit power, and report the instruction pattern to the MS. On the other hand, when the receive SIR is larger than the reference SIR, the control is made to set a TPC bit in the down signal to an instruction pattern to decrease the MS transmit power, and report the instruction pattern to the MS. If the MS is simultaneously connected to a plurality of BTSs, the MS receives TPC bit patterns independently set by the BTSs. When the MS receives different types of TPC bit patterns from the BTSs, that is, when one BTS requests an increase of transmit power and the other BTS requests a decrease of transmit power, the control is made to

It is necessary to set the reference SIR to a minimum value required to achieve a desired level of speech communication quality. However, an optimal value of the reference SIR varies depending upon a propagation environment. Further, when the MS is connected to the plurality of BTSs, an RNC (Radio Network Controller) performs selection/synthesis processing of an up receive signal from each of the BTSs. An optimal value of the reference SIR varies depending upon a variation in gain obtained by the selection/synthesis. When the reference SIR is set to a larger value than is necessary, excessive communication quality causes excessive MS transmit power, resulting in an increased interference with other users. Alternatively, when the reference SIR is too small, it is impossible to achieve the desired level of communication quality after the selection/synthesis in the RNC. Hence, another control has been studied of adaptively changing the reference SIR so as to maintain a constant level of communication quality.

20 An illustrative study of the prior art reference SIR control method is disclosed in "Outer Loop Algorithm of Transmit Power Control in CDMA Cellular System" IEICE General Meeting Report B-5-145, The Institute of Electronics, Information and Communication Engineers (1999). A periodical control method and
25 an immediate control method are shown as the control algorithm. In the former method, a control is made to vary the reference SIR depending upon a result of measurement of a frame error rate (FER). The control includes the steps of finding the FER at intervals of the predetermined number of frames, and comparing the FER with a
30 desired FER to increase the reference SIR if the measured FER is

of changing the reference SIR as fast as possible according to the circumstances so as to avoid quality degradation due to a delayed control of increasing the reference SIR, and excessive MS transmit power due to a delayed control of decreasing the reference SIR.

5

SUMMARY OF THE INVENTION

In view of the foregoing problems, it is an object of the present invention to provide a transmit power control method in a CDMA mobile communication system, of changing at a high speed a
10 reference SIR used for reference in a high-speed closed loop control of an up link.

According to the present invention, for achieving the above-mentioned objects, there is provided a transmit power control method in a CDMA mobile communication system including the
15 checking step of checking whether one or more base transceiver stations (BTSs) are connected, the calculating step of, when a result of the checking step shows that two or more BTSs are connected, selecting CH receive SIRs (Signal to Interference Ratios) corresponding to the connected BTSs, and making a calculation by
20 using the selected values, the reference value changing step of changing a value of a reference value S_{ref} according to a result of calculation, the upper limit setting step of, when the result of the checking step shows that only one BTS is connected, setting the reference value S_{ref} to an upper limit, and the reporting step of
25 reporting the changed reference value S_{ref} to all the connected BTSs in each of the steps. In the method, it is possible to decide the reference value S_{ref} in response to a variation in selection/synthesis gain due to an increase or a decrease of the number of connected BTSs.

30 Preferably, the CH receive SIR is any one of a Perch CH receive

09680278-100000

Preferably, the calculation made by using the selected value in the calculating step includes any one of the step of selecting the maximum value S_{max} and the second largest value S_{scd} from among the CH receive SIRs corresponding to the connected BTSs and the step of selecting the maximum value S_{max} from among the CH receive SIRs corresponding to the connected BTSs, and any one of the step of calculating a difference (X) between the S_{max} and the S_{scd} and the step of calculating the number (Nbts) of BTSs in which a difference between the S_{max} and the receive SIR becomes a predetermined value T2 or less.

Preferably, when the X is equal to a predetermined threshold value T1 or more, it is decided that only a small gain can be obtained by selection/synthesis, thereby setting the reference value Sref to an upper limit irrespective of results of the steps.

Preferably, when the X is equal to a predetermined threshold value T1 or less, it is decided that a sufficient gain can be obtained by selection/synthesis, thereby setting the reference value Sref to a value according to the X.

$$S_{ref} = S_{ref0} - (T1 - X) \times$$

T1 is a predetermined threshold value, and

Sref0 is an upper limit.

BRIEF DESCRIPTION OF THE DRAWINGS

The objects and features of the present invention will become
5 more apparent from the consideration of the following detailed
description taken in conjunction with the accompanying drawings in
which:

embodiment.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

A detailed description will now be given of preferred embodiments of a transmit power control method in a CDMA mobile communication system according to the present invention referring to the accompanying drawings. Figs. 1 to 10 show one embodiment of the transmit power control method in the CDMA mobile communication system of the present invention.

Embodiment 1

Referring to Fig. 1, the first embodiment is applied to the CDMA mobile communication system including a mobile station (hereinafter abbreviated as MS) 101, a base transceiver station (hereinafter abbreviated as BTS) 201, and a radio network controller (hereinafter abbreviated as RNC) 301. The BTS 201 includes a signal processing portion 205 having a modulator/demodulator portion (modem) 208, an SIR measuring portion 209, a transmit power controlling portion 210, and a reference SIR setting portion 211, an interface portion 207, a controlling portion 206, a TRX 204, an AMP 203, and an antenna 202. The RNC 301 includes a diversity handover trunk (DHT) 303 having a reference SIR deciding portion 304, a Perch CH receive quality observing portion 305, and a selection/synthesis processing portion 306, and an interface portion 302.

The interface portions 207 and 302 have an interface function between the plurality of BTSs 201 and the RNC 301. The controlling portion 206 has a call processing function and the function of controlling a state of the BTS 201. The MODEM portion 208 performs base band processing such as data error-correcting coding, data demodulation, diffusion modulation with respect to transmit data, and synchronous processing, back-diffusion, and data

demodulation with respect to receive data.

The SIR measuring portion 209 measures a signal to interference ratio (hereinafter abbreviated as SIR) of a receive signal. The transmit power controlling portion 210 decides a TPC bit pattern
5 depending upon a reference SIR reported from the reference SIR deciding portion 304 of the RNC 301 and a receive SIR reported from the SIR measuring portion 209.

The MODEM portion 208 adds to a down transmit signal a TPC bit reported from the transmit power controlling portion 210. The
10 TRX (frequency converter) 204 converts frequency. The AMP (amplifier) 202 has the function of amplifying power. The Perch CH receive quality observing portion 305 of the DHT (Diversity Handover Trunk) 303 observes a Perch CH receive SIR of an inform channel reported by the MS 101 to calculate a receive SIR for each of
15 the connected BTSs.

The reference SIR deciding portion 304 decides a reference SIR for the MS 101 on the basis of Perch CH receive SIR information for each of the connected BTSs reported by the Perch CH receive quality observing portion 305, and reports the result to the transmit power
20 controlling portion 210 of the BTS 201. The selection/synthesis processing portion 306 performs selection/synthesis processing of an up receive frame if the MS 101 is in communication with the plurality of BTSs 201.

Referring now to Figs. 1 and 2, a detailed description will be
25 given of an illustrative whole operation in a method of transmitting transmit power in the first embodiment of the present invention.

The MS 101 measures the Perch CH receive SIR transmitted from the peripheral BTS 201, and uses an up signal to periodically inform the RNC 301 of the measured receive SIR through the BTS
30 201. A Perch CH is an inform channel transmitted from each of the

5

10

15

25

algorithm in the reference SIR deciding portion 304 with reference to the flow chart shown in Fig. 2. In the flow chart, i denotes the BTS connected to the MS 101, and M is the number of BTSs. If M is two or more (Step S1), the maximum value S_{\max} and the second largest value S_{scd} are selected from among Perch CH receive SIRs (hereinafter referred to as $S_p(i)$ where $i = 1, 2, \dots, M$) corresponding to the connected BTSs (Step S2).

A gain of selection/synthesis obtained in the selection/synthesis processing portion 306 can be estimated by finding a difference X between the maximum value S_{\max} and the second largest value S_{scd} among the Perch CH receive SIRs (Step S3). The selection/synthesis means an operation in which, when the MS 101 is in communication with the plurality of BTSs, a frame having good quality is selected from among the receive frames in an up signal transmitted from each of the BTSs 201 to the RNC 301.

A description will now be given of the selection/synthesis when an MS 11 is connected to two BTSs, i.e., a BTS 13 and a BTS 12 shown by Figs. 3 and 4. As shown in Fig. 3, the MS 11 may be positioned relatively near the BTS 12 with good radio propagation characteristic between the MS 11 and the BTS 12, and poor radio propagation characteristic between the MS 11 and the BTS 13. In this case, an RNC 14 receives from the BTS 12 an up receive frame including fewer errors, and receives from the BTS 13 an up receive frame including greater errors. Thus, there is a high probability that the selection/synthesis processing portion 306 selects the receive frame from the BTS 12 from among the receive frames transmitted from the BTS 12 and the BTS 13.

On the other hand, as shown in Fig. 4, the MS 11 may stay at a substantially intermediate position between the BTS 13 and the BTS 12 with the same error ratio in the receive frame. In this case, the

selection/synthesis processing portion 306 can select each of the receive frames from the BTS 12 and the BTS 13 with the substantially same probability. As illustratively shown in Fig. 4, as a difference in propagation state between the connected BTSs is smaller, the gain of selection/synthesis becomes larger. With a larger gain obtained by the selection/synthesis, it is possible to reduce by the gain the reference SIR set for each of the connected BTSs. Hence, the reference SIR (hereinafter referred to as Sref) is defined as a function of X as shown in the formula (1) (Step S4):

$$S_{ref} = F(X) \quad \dots(1)$$

Fig. 5 shows an illustrative function F(X). If X is more than a threshold value T1, it is decided that a small gain can be obtained by the selection/synthesis. Thus, the following expression is used:

$$S_{ref} = S_{ref0} \quad \dots(2)$$

where Sref0 is a reference SIR on the assumption that no selection/synthesis is performed, and serves as an upper limit of Sref. If X is equal to the threshold value T1 or less, it is decided that a sufficient gain can be obtained by the selection/synthesis. Then, Sref is defined as a value according to X as shown in the following expression:

$$S_{ref} = S_{ref0} - (T1 - X) \times \alpha \quad \dots(3)$$

Where α is a desired constant.

As X is smaller, Sref is set to a larger value. Further, when no selection/synthesis is performed because one BTS is connected (M =

1), Sref is set to an upper limit depending upon the expression (2) (Step S5).

After Sref is changed according to the above steps, the reference SIR deciding portion 304 reports Sref to each of the
5 connected BTSs 201 (Step S6). Since it is decided by using the Perch CH receive SIR information whether or not the reference SIR should be changed, it is possible to respond to a variation in selection/synthesis gain due to an increase or decrease of the number of connected BTSs at a higher speed than that in the prior art control
10 method (a periodical control method, or an immediate control method).

It is the first effect to prevent degradation of speech communication quality by increasing the reference SIR at a high speed when the selection/synthesis gain in the RNC is decreased.
15 This is because it is possible to detect a decrease of the selection/synthesis gain at a high speed by observing the Perch CH receive SIR reported from the MS at regular intervals.

It is the second effect to, when the selection/synthesis gain in the RNC is increased, reduce power interfering with other users by
20 decreasing the reference SIR at a high speed. This is because it is possible to detect an increase of the selection/synthesis gain at a high speed by observing the Perch CH receive SIR reported from the MS at regular intervals.

It is the third effect that it is possible to use the optimal value
25 of the reference SIR in consideration of the selection/synthesis gain even when, after the MS is switched to discrete communication CHs, the MS is connected to the plurality of BTSs to perform the selection/synthesis. This is because it is possible to measure the Perch CH receive SIRs transmitted from the sectors at all times
30 before the MS is switched to the communication CHs, and previously

09680278-100600

decide the reference SIR depending upon the measured receive SIR.

Embodiment 2

A description will now be given of embodiment 2 of the present invention referring to Figs. 1 and 6. Referring to the block diagram of Fig. 1, the embodiment 2 is identical with the embodiment 1 except that a reference SIR deciding portion 304 selects the maximum value from among Perch CH receive SIRs corresponding to connected BTSs, reported from a Perch CH receive quality observing portion 305, and calculates the number of connected BTSs (hereinafter referred to as Nbts) in which a difference between the maximum value and the receive SIR becomes equal to a threshold value or less, thereby deciding depending upon Nbts whether or not the reference SIR should be changed. If Nbts is two or more, a current reference SIR is changed according to Nbts. If Nbts is one or only one BTS is connected, the reference SIR is set to an upper limit Sref0. The reference SIR deciding portion 304 reports the changed reference SIR to a transmit power controlling portion 210 of a BTS 201.

Referring now to the flow chart of Fig. 6, a description will be given of a reference SIR deciding algorithm employed in the reference SIR deciding portion 304. In the flow chart, i denotes the BTS connected to an MS 101, and M is the number of BTSs. If M is two or more (Step S1), the maximum value S_{max} is selected from among Perch CH receive SIRs (hereinafter referred to as $S_p(i)$ where $i = 1, 2, \dots, M$) corresponding to the connected BTSs (Step S22). Subsequently, a difference between S_{max} and $S_p(i)$ except S_{max} is compared with a predetermined threshold value $T2$ according to the following formula (4) to calculate the number Nbts of connected BTSs (Step S23):

$$S_{\max} - S_p(i) \quad T_2 \quad \dots(4)$$

The Nbts obtained by the calculation using above formula (4) means the number of BTSs having similar propagation path characteristic among the connected BTSs. As Nbts is larger, a gain of selection/synthesis becomes greater. Therefore, it is possible to decrease the reference SIR set for each of the connected BTSs. Then, the reference SIR is defined as a function of Nbts as follows:

$$S_{\text{ref}} = F(\text{Nbts}) \quad \dots(5)$$

Fig. 7 shows an illustrative relationship between Nbts and Sref shown by the function $F(\text{Nbts})$ according to the formula (5). For $\text{Nbts} = 0$, Sref becomes an upper limit Sref0. As Nbts is more increased, the gain of the selection/synthesis is more increased. Hence, Sref should be decreased (Step 24).

$$F(0) > F(1) > F(2) \quad \dots(6)$$

The Perch CH receive SIRs are used to calculate the number of connected BTSs in which the selection/synthesis gain can be obtained, and it is decided depending upon the number of BTSs whether or not the reference SIR should be changed. Thus, it is possible to change the reference SIR at a higher speed than that in the prior-art control method.

Alternatively, in the embodiment 2, a difference X between the maximum value S_{\max} and the second largest value S_{scd} of $S_p(i)$ may be calculated as in the first embodiment, and Sref may be defined as the above-mentioned function of Nbts and X. The relationship can be written in the following formula (7):

$$S_{ref} = F(N_{bts}, X) \quad \dots(7)$$

The constant α of the formula (3) discussed in the first embodiment may be varied according to N_{bts} . For example, the
5 constant α may be more increased as N_{bts} becomes larger. In such a manner, by using both of N_{bts} and X as parameters of the function, it is possible to provide a more strict control in response to a variation in gain by the selection/synthesis.

10 Embodiment 3

A description will now be given of the embodiment 3 of the present invention referring to Figs. 8 and 9. Referring to the block diagram of Fig. 8, the embodiment 3 differs from the embodiment 1 in that a communication CH receive quality observing portion 405
15 observes receive SIR information of an up communication CH, reported from a connected BTS 201, and depending upon the receive SIR information of the up communication CH, reported from the communication CH receive quality observing portion 405, it is decided in a reference SIR deciding portion 304 whether or not a
20 reference SIR should be changed.

The reference SIR deciding portion 304 compares the sizes of the reported up communication CH receive SIRs corresponding to the connected BTSs to select the maximum SIR and the second largest SIR. If a difference between the maximum SIR and the second
25 largest SIR is equal to a threshold value or less, the reference SIR is decreased according to the difference between the SIRs. If the difference between the maximum SIR and the second largest SIR is more than the threshold value or only one BTS is connected, the reference SIR is set to an upper limit. The reference SIR deciding
30 portion 304 reports the changed reference SIR to the transmit power

Referring now to the flow chart of Fig. 9, a description will be given of a reference SIR deciding algorithm employed in the reference SIR deciding portion 304. The embodiment 3 differs from the embodiment 1 in that the maximum value S_{max} and the second largest value S_{scd} are selected from among up communication CH receive SIRs corresponding to the connected BTSs in Step S32. A gain of selection/synthesis obtained in the selection/synthesis processing portion 306 can be estimated by finding a difference X between the maximum value S_{max} and the second largest value S_{scd} among the communication CH receive SIRs (Step S33). Then, S_{ref} is defined as a function of X as follows (Step 34):

15

Embodiment 4

A description will now be given of the embodiment 4 of the
30 present invention referring to Figs. 8 and 10. Referring to the block

diagram of Fig. 8, the embodiment 4 differs from the embodiment 2 in that a communication CH receive quality observing portion 405 observes receive SIR information of an up communication CH, reported from a connected BTS 201, and based on the receive SIR information of the up communication CH, reported from the communication CH receive quality observing portion 405, it is decided in a reference SIR deciding portion 304 whether or not a reference SIR should be changed.

A reference SIR deciding portion 304 selects the maximum value from among up communication CH receive SIRs corresponding to connected BTSs, reported from a Perch CH receive quality observing portion 305, and calculates the number of connected BTSs (Nbts) in which a difference between the maximum value and the receive SIR becomes equal to a threshold value or less, thereby deciding depending upon Nbts whether or not the reference SIR should be changed. If Nbts is two or more, a current reference SIR is changed according to Nbts. If Nbts is one or only one BTS is connected, the reference SIR is set to an upper limit. The reference SIR deciding portion 304 reports the changed reference SIR to a transmit power controlling portion 210 of a BTS 201.

Referring now to the flow chart of Fig. 10, a description will be given of a reference SIR deciding algorithm employed in the reference SIR deciding portion 304. In the flow chart, i denotes the BTS connected to an MS 101, and M is the number of BTSs. If M is two or more (Step S1), the maximum value S_{max} is selected from among up communication CH receive SIRs corresponding to the connected BTSs (Step S42). Subsequently, a calculation is made to find the number Nbts of connected BTSs in which a difference between S_{max} and the up communication CH receive SIR except S_{max} becomes equal to a predetermined threshold value $T2$ or less (Step S23). As

5

10

20

25

corresponding to the connected BTSs, and making the calculation by using the selected values, and the step of changing the value of the reference value S_{ref} according to the result of calculation. The method also includes the step of, when the result of the checking step

5 shows that only one BTS is connected, setting the reference value S_{ref} to the upper limit, and the step of reporting the changed reference value S_{ref} to all the connected BTSs in each of the steps. Therefore, it is possible to change the reference SIR at a high speed in response to the variation in selection/synthesis gain due to the

10 increase or the decrease of the number of connected BTSs.

While preferred embodiments of the present invention have been described using specific terms, such description is for illustrative purposes only, and it is to be understood that changes and variations may be made without departing from the spirit or

15 scope of the following claims.
